Lehrstuhl für Informatik 1

20:11 Uhr, den 29. November 2016
Inhalt I

1. Colorings I
   - Cycle
   - Trees

2. Eulerian cycle
   - Introduction
   - Introduction
   - The algorithm

3. Matchings
   - Introduction
   - Algorithm
   - Running times

4. Colorings II
   - Bipartite graphs
   - $\Delta + 1$ Coloring any Graph

5. MIS
   - Introduction
   - MIS and Coloring

6. Coloring III
   - Outerplanar graphs

7. Simulations
   - Simple simulations
   - Advanced simulations
Colorings

**Coloring Problem**

- Given undirected graph $G = (V, E)$ and $k \in \mathbb{N}$.
- Compute [exists?] Function $c : V \mapsto \{1, \cdots, k\}$ with:
  - $\forall \{a, b\} \in E : c(a) \neq c(b)$.
- Coloring number (chromatic index) of $G$:
  - $\chi(G) := \min\{\{k \mid \exists c : V \mapsto \{1, \cdots, k\} \mid \forall \{a, b\} \in E : c(a) \neq c(b)\}\}$.

- Coloring problem is NP-complete.
- Let $G = C_n$, i.e. $G = (\{v_0, \cdots, v_{n-1}\}, \{\{v_i, v_{(i+1) \mod n}\} \mid 0 \leq i < n\})$.
- Then we have $\chi(C_n) \leq 3$ and $\chi(C_{2\cdot n}) \leq 2$ ($\chi(C_{2\cdot n+1}) = 3$).
- We do not have a nice order on the nodes:
- let $\pi(i)$ be a permutation
- Let $G = C_n$, i.e. $G = (\{v_0, \cdots, v_{n-1}\}, \{\{v_{\pi(i)}, v_{\pi((i+1) \mod n)}\} \mid 0 \leq i < n\})$. 
Parallel Coloring Algorithm of (on) a cycle (Idea)

- A processor $P_i$ works on $v_{\pi(i-1)}$ for some permutation $\pi$.
- Register $R_i$ holds $\pi(i - 1)$.
- Register $N_i$ holds $\pi(i)$.
- In register $C_i$ will be the color of $v_{R_i}$.
- Initialize $C_i$ with $i$.
- Reduce step by step the number of colors.
- We will use the colors $\{0, 1, \cdots, n\}$. 
Parallel Coloring Algorithm of (on) a cycle (Idea)

Programm: color-cycle

for all $P_{i+1}$ where $0 \leq i < n$ do in parallel

$\pi(i - 1) \rightarrow R_i$

$\pi(i) \rightarrow N_i$

$c = i$

$c \rightarrow C_i$

repeat $\lceil \log^*(n) \rceil + 2$ times

$C_{N_i} \rightarrow c'$

minimal $k$ with: $((c \gg k) \mod 2) \neq ((c' \gg k) \mod 2)$.

$c = 2 \cdot k + ((c \gg k) \mod 2)$.

$c \rightarrow C_i$
Parallel Coloring Algorithm of (on) a cycle (Idea)

- At the start we are using $n$ colors.
- Within each color-reduction will the coloring stay correct.
- Within each color reduction will the coloring number be reduced from $x$ to $\log(x) + O(1)$.
- After $[\log^*(n)]$ reductions steps will be the coloring numbers $\leq 5$.
- A second reduction of colors will follow now:
The rows hold \( c \) and the columns hold \( c' \).

The entries in the table hold the new \( c \).

\[ c \rightarrow C_i \]
Theorem:
A cycle with $n$ nodes could be colored with $n$ processors in time $O(\log^* n)$ with at most 3 colors.

Proof: see above.

Theorem:
A cycle of $n$ processors may color itself in time $O(\log^* n)$ with at most 3 colors.

Proof: see above.

Theorem:
A cycle of $n$ processors needs at least $\Omega(\log^* n)$ time to color itself with at most 3 colors.

Proof: see V4.
Coloring a Tree

- A processor $P_i$ works on $v_{\pi(i-1)}$ for some permutation $\pi$.
- Register $R_i$ holds $\pi(i - 1)$.
- Register $N_i$ holds $\pi(j - 1)$ where $j$ is the father of $i$.
- The father of the root $r$ is $r$.
- In register $C_i$ will be the color of $v_{R_i}$.
- Initialize $C_i$ with $i$.
- Reduce step by step the number of colors.
- We will use the colors $\{0, 1, \cdots, n\}$.

Coloring a Tree

**Theorem:**
A tree with \( n \) nodes could be colored with \( n \) processors in time \( O(\log^* n) \) with at most 3 colors.

Proof: see above.

**Theorem:**
A tree of \( n \) processors may color itself in time \( O(\log^* n) \) with at most 3 colors.

Proof: see above.
Eulerian cycle

Definition:
A graph $G = (V, E)$ is called Eulerian, iff there exists a cycle which visits each edge precisely once.

Theorem
A non-directed graph $G = (V, E)$ is Eulerian
- $G$ is connected and
- each node of $G$ has even degree.

Theorem
A directed graph $G = (V, E)$ is Eulerian
- $G$ is strongly connected and
- each node has as many incoming edges as outgoing ones.

Problem: Compute Eulerian cycle on Eulerian graphs.
Idea

- Non Parallel:
  - Start with a free edge and follow free/unused edges till a cycle is closed.
  - Repeat till all edges are in some cycle.
  - Join pairs of cycles into a single one.
  - Repeat till just one cycle remains.

- If $G$ is non-directed, then make a directed version of $G$.
- Compute a cover of cycles.
- Compute an additional cycle which meets each cycle precisely once.
- Uses these to compute a cycle for $G$.
- Delete some edges to get a Eulerian cycle for $G$. 
Change a non-directed Graph into a directed one

- G contain \( m \) non-directed edges.
- Substitute each non-directed edge with two directed ones: \( \{i, j\} \) becomes \((i, j)\) and \((j, i)\).
- Define a successor for each edge:
  - The neighbors of \( v \) are: \( v_0, v_1, \ldots, v_{d-1} \).
  - Then define for all \( i \):
    \[
    \text{Succ}((v_i, v)) := (v, v_{(i+1) \mod d}) \quad \text{und} \quad \text{Succ}((v_{(i+1) \mod d}, v)) := (v, v_i).
    \]
- Each directed edge is in precisely one cycle (defined by \( \text{Succ} \)).
- For each cycle \( C \) exists one cycle \( C' \), which consists the reverse edges.
- We will now delete one of the two cycles \( C \) or \( C' \).
Generating a directed Graph

- Identify the generated cycles:
  - Let \( \min(((i, j), (k, l))) := \begin{cases} (i, j) & \text{if } i \leq k \lor i = k \land j < l \\ (k, l) & \text{otherwise} \end{cases} \).
  - For each edge \( e \) define \( \text{Edge}'(e) = e \);
  - For all edges \( e \) repeat \( \log m \) times:
    - \( \text{Edge}'(e) = \min(\text{Edge}'(e), \text{Edge}'(\text{Succ}(e))) \)
    - \( \text{Succ}(e) = \text{Succ}(\text{Succ}(e)) \).
  - For each edge \((i, j)\): if \( \min(((i, j), (j, i))) \neq (i, j) \) then let \( \text{Edge}'(e) = 0 \).
  - Thus we have selected for each non-directed edge a directed one (resp. a direction).
  - Possible with \( m \) in time \( O(\log m) \).
  - We consider in the following on directed graphs.
Step 1

- Let $G = (V, E)$ be a directed graph.
- Sort the edges into an array $Edge$.
  using the order: $(i, j) < (k, l) \iff j < l \lor (j = l \land i < k)$.
- Sort the edges into an array $Succ$.
  using the order: $(i, j) < (k, l) \iff i < k \lor (i = k \land j < l)$.
- We have already defined the cycles:
  Successor of edge $e = Edge(i)$ is the edge $Succ(i)$.
- We also store in $P(i)$ the position of $Succ(i)$ in $Edge$.
- I.e. $Edge(P(i)) = Succ(i)$.
- This information could be updated during the sorting of $Succ$.
- This could be done in time $O(\log m)$ using $O(m)$ processors.
Step 2

- **Situation:** We have a directed graph covered by cycles.
- **Problem:** Compute for each edge $e$ the cycles where $e$ belongs to.
- **Solution:** compute for each cycle the minimal edge 

\[
((i, j) < (k, l) \iff i < k \lor (i = k \land j < l)).
\]
- **Algorithm:**

```
Programm:

for all $P_i$ where $1 \leq i \leq m$ do in parallel
CycleRep(i) := Succ(i)
    for $i := 1$ to $\lceil \log m \rceil$ do:
        CycleRep(i) := min(CycleRep(i), CycleRep(P(i)))
        P(i) := P(P(i))
```

- We use again the doubling technique.
- Possible in time $O(\log m)$ using $O(m)$ Processors.
Step 2 (Continued)

- Situation: the cycles of the coverage are identified by *CycleRep*.
- Problem: join the cycle into a single one.
- Solution: Identify the nodes of the cycle.

\[ C = \{ CycleRep(i) \mid 1 \leq i \leq m \} \text{.} \text{(Note } C \text{ is a edge set)} \]

\[ G' = V \cup C \]

\[ E' = \{ (u, v) \mid u \in V, v \in C : v \text{ is identified in the cycle by } u \} \]

Computing of \( E' \):

Programm:

\[ \text{for all } P_i \text{ where } 1 \leq i \leq m \text{ do in parallel} \]

\[ (u, v) = Edge(i) \]

\[ Edge'(2 \cdot i) = (u, CycleRep(i)) \]

\[ Edge'(2 \cdot i + 1) = (v, CycleRep(i)) \]
Step 2 (Continued)

- Situation: Cover of cycles and graph $G'$ defined.
- Problem: there are multiple edges.
- Solution: sort them out.
- Sort $Edge'$.
- Programm:
  
  ```
  for all $P_i$ where $1 \leq i \leq m$ do in parallel
  if $Edge'(i) = Edge'(i + 1)$ then $Edge(i) = \infty$
  ```
- Sort $Edge'$.
- Consider only the first $|E'|$ elements of $Edge'$.
- Problem: node $u$ could appear several times in a cycle $v$.
- As before we may compute a single representative.
- Let these edge be $(i, u) = Cert(u, v)$.
- May be done in time $O(\log m)$ using $O(m)$ processors.
Step 3

- Situation: Covering of the cycles and graph $G'$ computed.
- Problem: Compute cycle in $G'$.
- Solution: compute spanning tree $T$ for the bipartite Graph $G'$.
- To compute spanning tree we need $O(\log^2 m)$ time with $O(m/\log^2 m)$ Processors.
- Then we substitute each edge in $T$ with two directed edges.
- The new graph $T'$ is Eulerian.
- The Eulerian cycle is easy to find:
- To do so, compute for each node of the tree the order of edges.
- Could be don in time $O(\log m)$ using $O(m)$ processors.
Step 4

- **Situation:** We have a cover of cycles for $G$ and $T'$.
- **Problem:** Find cycle $L$ in $G'$.
- **Solution:** Combine the cycles using $Cert(u, v)$.
- $L$ will also contain the Eulerian cycle in $G$.
- For each cycle $v$ in $G$ $Cert(u, v)$ gives us an edge, at which we may exchange between $v$ and the cycle in $T'$.
- These points of change will be used to construct a single cycle $L$.
- Time $O(1)$ using $O(m)$ Processors.
Step 5

- **Situation:** we have a cycle for $G$ and $T'$.
- **Problem:** find cycle in $G$.
- **Solution:** delete edges from $T'$.
- **Programm:**
  
  ```java
  for all $P_i$ where $1 \leq i \leq m$ do in parallel
  if Succ($i$) $\in T'$ then Succ($i$) := Succ(Succ($i$))
  if Succ($i$) $\in T'$ then Succ($i$) := Succ(Succ($i$))
  ```

- Uses time $O(1)$ with $O(m)$ processors.
- Total time is: $O(\log^2 m)$ using $O(m)$ processors.
- Also possible: $O(\log^2 m)$ time using $O(m/\log^2 m)$ processors.
Definition

Let $G = (V, E)$ be a non-directed graph.

- $M \subset E$ is called a matching, iff $\forall e, e' \in M : e \cap e' = \emptyset$.
- $M$ is called maximal matching, iff $\nexists e \in E : M \cup \{e\}$ is a matching.
- $M$ is called maximum matching, iff for all matchings $M'$ we have $|M'| \leq |M|$.

Sequential: $O(m \log m)$ for maximal matching.

Idea: Choose any free edge and delete all incident edges.

Sequential: $O(m^3)$ for maximum matching.

Idea: enlarging alternating pathes.
Idea

- Let $\Delta(G)$ be the maximal degree of $G$.
- Enlarge the matching step by step by several edges.
- There will be $O(\log_{3/2} n)$ phases.
- $i$-te phase $F_i$ has $G_i$ as input and will output $M_i$.
- $G_1 = G$ and final result: $\bigcup M_i$.
- Within each phase $F_i$ we will call the procedure $DegreeSplit$ $(1 + \log(\Delta(G)))$-times.
- Within each step within a phase we will half the node degree.
- We denote with $G(i, j)$ the graph considered in the $j$-th Step of the $i$-th phase.
- We will describe the procedure $DegreeSplit$.
- Let $k$ be the smallest number with $2^k \leq \Delta(G) \leq 2^{k+1}$.
- We will call all nodes $v$ with $\delta(v) \geq 2^k$ active.
Step 1

- Compute all active nodes of $G(i,j)$
  - Determine the degree in time $O(\log \Delta(G(i,j)))$ with $O(m)$ processors.
  - Determine the maximum degree in time $O(\log n)$ with $O(n)$ processors.
  - Then the active nodes are known in time $O(1)$ using $O(n)$ processors.
- Total running time: $O(\log n)$ using $O(m)$ processors.
Step 2

- Compute the graph $G^*(i, j)$ as follows:
  - Compute all nodes that are incident to active nodes.
  - Determine the new node degree.
  - If there are nodes with odd degree connect them to a new node $v$.

- Total running time: $O(\log n)$ using $O(m)$ processors.
- $G^*(i, j)$ might not be connected.
- Each component of $G^*(i, j)$ contains an Eulerian cycle.
- Note that each node $v$ has even degree.
Step 3

- Compute an Eulerian cycle on each component of $G^*(i, j)$.
- This needs time $O(\log^2 n)$ with $O(m + n)$ processors.
- Note that the additional $n$ processors result from the additional edges.
- Label the edges from the Eulerian cycle alternating with 0 and 1.
- For the component with the additional node $v$ start with $v$ using label 0.
- For all other components start at an arbitrary node with label 1.
- Running time: $O(\log n)$ with $O(m + n)$ processors.
- Use Parallel Prefix to compute the labels.
Step 4

- Delete all edges with label 0.
- If the remaining graph $G^{**}(i,j)$ is not a matching then $G(i,j + 1) = G^{**}(i,j) \setminus \{v\}$.
- If the remaining graph $G^{**}(i,j)$ is a matching then $M_i = E(G^{**}(i,j))$.
- Running time: $O(1)$ with $O(m + n)$ processors.
- Running time of the procedure $DegreeSplit$: $O(\log^2 n)$ with $O(m + n)$ processors.
- It remains to show: After at most $1 + \log(\Delta(G(i,j)))$ steps $DegreeSplit$ computes a matching.
- It remains to show: After at most $O(\log_{3/2} n)$ phases the matching is optimal.
**Lemma:**

Let $G$ be the input of $DegreeSplit$, then $DegreeSplit$ will compute a matching after $1 + \log(\Delta(G))$ iterations.

**Proof:**

- Let $k$ be the smallest number with $2^k \leq \Delta(G) \leq 2^{k+1} + 1$.
- Let $G_1$ be the result of an iteration.
- Let $v$ be active in $G$. It holds:
  - $2^k \leq \delta_G(v)$.
  - $\lfloor \delta_G(v)/2 \rfloor \leq \delta_{G_1}(v) \leq \lceil \delta_G(v)/2 \rceil + 1$.
  - $2^{k-1} \leq \delta_{G_1}(v) \leq 2^k + 1$.
- Then $v$ stays active in $G_1$.
- Hence the degree is halved in every step.
- There exists a $k' \leq k$ such that $G_{k'}$ has a degree of 3.
- After two more iterations the degree is at most one.
- So a matching is found.
Lemma:
A logarithmic number of phases is enough to compute a maximum matching.

Proof:
- Let $A_i$ be the nodes that are active in phase $F_i$.
- Then $A_i$ is a vertex cover of $G_i$.
- \((C \subset V \text{ is a vertex cover if } \forall e \in E : e \cap C \neq \emptyset)\)
- We show the following;
  - Half of the nodes in a vertex cover $A_i$ can be made incident to edges from $M_i$.
  - This means it holds: \( |A_i/G_{i+1}| \leq |A_i|/2 \).
    with $A_i/G_{i+1}$ the nodes of $A_i$ in $G_{i+1}$
  - There are vertex covers $C_i$: \( |C_{i+1}| \leq 2 \cdot |C_i|/3 \).
Outer loop (Proof)

- Let $G_k = (V, E_k)$ be the graph in the third to last loop of $DegreeSplit$.
- W.l.o.g. $G_k$ is connected with degree $\leq 3$.
- $DegreeSplit$ can w.l.o.g. remove the smallest set of edges.
- Hence it holds $|M_i| \geq |E_k|/4$. 
Outer loop (Proof)

- If $|E_k| \geq |A_i|$ then $M_i$ contains at least $|A_i|/4$ edges.
  - Both end points of an edge from $A_i$ belong to $A_i$ and
  - at least half of them are incident to $M_i$.

- If $|E_k| < |A_i|$ then $G_k$ is a tree.
  - We remove edges from $G_k$ that have a leaf as one of its end points.
  - Furthermore the incident edges are removed.
Outer loop (Proof)

- Because $\Delta(G_k) \leq 3$ at most 2 trees $T_1$ and $T_2$ remain (with $n_1 + n_2$ nodes).
- Then $((n_1 - 1) + (n_2 - 1))/4$ edges are added to $M_i$.
- Then $M_i$ contains $|A_i|/2$ nodes.
- Then it holds: $|A_i/G_{i+1}| \leq |A_i|/2$. 
Outer loop (Proof)

- We show using induction that $G_i$ contains a vertex cover $C_i$ with $|C_i| \leq (2/3)^{i-1}|V|.$
- We will show that $|C_{i+1}| \leq 2|C_i|/3.$
- Basis: $i = 1$: Choose $C_1 = V$.
- Case 1: $|A_i| \leq 4|C_i|/3$.
  - In phase $i$ half of the nodes are removed from $A_i$.
  - $A_i/G_{i+1}$ is a vertex cover from $G_{i+1}$.
  - $|A_i|/2 \leq (4|C_i|/3)/2 = 2|C_i|/3$.
- Case 2: $|A_i| > 4|C_i|/3$.
  - Half of the nodes from $A_i$ are removed.
  - These have end points in $M_i$.
  - $C_i$ is a vertex cover of $G_i$.
  - Then every edge has at least one end point in $C_i$.
  - At least $1/4$ of the edges in $A_i$ are contained in $C_i$.
  - $C_i/G_{i+1}$ is a vertex cover of $G_{i+1}$.
  - $|C_i/G_{i+1}| \leq |C_i| - |A_i|/4 \leq |C_i| - (4|C_i|/3)/4 = 2|C_i|/3$. 

\[
|M_i| \geq |E_k|/4
|A_i/G_{i+1}| \leq |A_i|/2
\]
Theorem:

A maximal vertex cover can be computed in time $O(\log^4 n)$ using $O(n + m)$ processors.

Proof:

- Outer loop: $O(\log n)$
- Inner loop: $O(\log n)$
- Running time of DegreeSplit: $O(\log^2 n)$. 
Bipartite graphs

A graph $G = (A, B, E)$ with $E \subseteq A \times B$ is called bipartite graph.

directed line graph

Let $G = (V, E)$ be a directed graph, then $G^2 = (E, F)$ with $F = \{((a, b), (b, c)) \mid (a, b), (b, c) \in E\}$ is the line graph of $G$.

undirected line graph

Let $G = (V, E)$ be an undirected graph, then $G^2 = (E, F)$ with $F = \{\{\{a, b\}, \{b, c\}\} \mid \{a, b\}, \{b, c\} \in E\}$ is the line graph of $G$.

Edge coloring

- Let $G = (V, E)$ be an undirected graph and $k \in \mathbb{N}$.
- Compute [Exists?] a $k$-coloring of $G^2$. 
Introduction

- Let $G = (V, E)$ be an undirected graph.
- It is NP-complete to find a $\Delta(G)$ edge coloring.
- There is always a $\Delta(G) + 1$ edge coloring.
- A bipartite graph $G$ is $\Delta(G)$ edge colorable.
- Or: A bipartite graph $G$ can be covered with $\Delta(G)$ matchings.
- Here: Parallel edge coloring of a bipartite graph.
- 1. Step: $\Delta(G) = 2^k$ for some $k \in \mathbb{N}$.
Method for $\Delta(G) = 2^k$

- Idea: Cover the edges of $G$ with cycles and paths.
- Color edges alternating with 0 and 1.
- This computes a partition of $G$ in $G_0$ and $G_1$ with $\Delta(G_0) = \Delta(G_1) = 2^{k-1}$.
- All steps can be done in time $O(\log n)$ with $O(m)$ processors.
- Continue recursively.
- Total running time: $O(\log^2 n)$ with $O(m)$ processors.
Example
Example
Example
Method for $\Delta(G) < 2^k$ (Idea)

- Color as many edges as possible in the sub graph $G'$ with $\Delta(G') = 2^{k'}$.
- Allow double coloring of edges, i.e. $(i, j)$ is colored $\alpha$ at $i$ and $\beta$ at $j$.
- Within each step it holds:
  - There are correctly colored edges and double colored edges.
  - The set of colors $S$ is chosen such that the number of double colored edges is as big as possible,
  - These edges become colored correctly.
  - This happens in the extended sub graph with $\Delta(G') = 2^{k'}$. 
Method for $\Delta(G) < 2^k$ (Idea)

- Let $k': 2^{k'} < \Delta(G) < 2^{k'+1}$, $C = \emptyset$ and $U = E$.
- Partition $F = \{0, 1, 2, \ldots, \Delta(G) - 1\}$ into four sets of almost the same size $S_1, S_2, S_3, S_4$.
- Repeat until all edges are colored correctly:
  - Choose double coloring of the edges from $U$.
  - Chose $i, j$ with: As many edges as possible from $U$ are colored with only $S_i \cup S_j$.
  - Let $U'$ be those edges.
  - It holds: $|U'| \geq |U|/6$ and $U' \leq 2^{k'}$.
  - Let $H$ be those edges that only use colors from $S_i \cup S_j$.
  - Let $G' = (V, H)$, extend $G'$ such that $\Delta(G') = 2^{k'}$.
  - Color $G'$ using the method from above.
  - Set $C = C \cup H$, these are the correctly colored edges.
- Total running time: $O(\log^3 n)$ with $O(m)$ processors.

Results

Theorem:

A bipartite graph $G$ with $\Delta(G) = 2^k$ can be edge colored with $\Delta(G)$ colors in time $O(\log^2 n)$ with $O(m)$ processors.

Proof: See above.

Theorem:

A bipartite graph $G$ can be edge colored with $\Delta(G)$ colors in time $O(\log^3 n)$ with $O(m)$ processors.

Proof: See above.
Results without proof

Lemma

Any graph $G = (V, E)$ with maximal degree $\Delta$ is $\Delta + 1$ colorable.

Lemma

Any graph $G = (V, E)$, which is not a clique nor a odd cycle is $\Delta$ colorable.

- Idea of distributed/parallel algorithm:
- Reduce recursively the colors.
- Double the size of correctly colored sub-graphs.
- Or use the idea for trees to bounded degree graphs.
Recall and Idea 1

Theorem:
A tree with $n$ nodes could be colored with $n$ processors in time $O(\log^* n)$ with at most 3 colors.

- Recall: choose minimal $k$ with: $((c \gg k)\%2) \neq ((c' \gg k)\%2)$ and
- set $c = 2 \cdot k + ((c \gg k)\%2)$.
- This did produce a 6-coloring on trees.
- On a bounded degree graph use this idea on a vector of length $\Delta$. 
Algorithm 1

choose minimal $k$ with: $((c \gg k) \% 2) \neq ((c' \gg k) \% 2)$ and set $c = 2 \cdot k + ((c \gg k) \% 2)$

1. Let $v_1, v_2, ..., v_d$ the $d \leq \Delta$ neighbors of $v$
2. Let $c_1, c_2, ..., c_d$ the colors $v_i$ and $c$ the color of $v$.
3. For each $i$ ($1 \leq i \leq d$) do
   1. choose minimal $k_i$ with: $((c \gg k_i) \% 2) \neq ((c_i \gg k_i) \% 2)$ and
   2. set $b_i = 2 \cdot k_i + ((c \gg k_i) \% 2)$.
4. Choose new color for $v$: $(b_1, b_2, ..., b_d)$.

- As before, the coloring stays valid.
- Like before, a $x$-bit coloring becomes a $\Delta(\log x + 1)$-bit coloring.
- Like before, we may reduce the colors to $\Delta + 1$ colors.
- For unbounded degree the running time becomes: $O(\log^* n + 2^\Delta)$. 
Theorems 1

choose minimal $k$ with: $((c \gg k)\%2) \neq ((c' \gg k)\%2)$ and set $c = 2 \cdot k + ((c \gg k)\%2)$

Theorem

A constant degree graph may be colored with $\Delta + 1$ colors in time $O(\log^* n)$ on a distributed system.

Theorem

A constant degree graph may be colored with $\Delta + 1$ colors in time $O(\log^* n)$ on a parallel system using $n$ processors.
Notations and Idea 2

choose minimal \( k \) with: \( ((c \gg k) \% 2) \neq ((c' \gg k) \% 2) \) and set \( c = 2 \cdot k + ((c \gg k) \% 2) \)

- \( x \) will be a binary string with up to \( k \) bits.
- Define \( U_x = \{(a_1, a_2, ... a_{k-|x|}, x) | a_i \in \{0, 1\}\} \).
- The procedure RecurseColor will color \( U_x \) with \( \Delta + 1 \) colors.
- Idea:
  - Having colored \( U_x \) with \( \Delta + 1 \) colors,
  - Recolor \( U_{1x} \) such that \( U_{0x} \) and \( U_{1x} \) are colored correctly.
  - This doubles the size of correctly colored sub-graphs.
Recursive Algorithm

RecurseColor(x) (initial with x = ε):

1. Let $ID = (a_1, a_2, ..., a_k)$ be a vector of bits, which identify the node/prozessor v.
2. Set $l = |x|$.
3. If $l = k$ then set $c(v) = 1$ and return.
4. Set $b = a_k - l$.
5. Set $c(v) = RecurseColor(bx)$.
6. If $b = 0$ then return.
7. For round $i$ from 1 to $\Delta + 1$ do
   
   1. if $c(v) = i$ then $c(v) = \min\{1, 2, \ldots, \Delta + 1\} \setminus \bigcup_{\{v, a\} \in E} \{c(a)\}$

$U_x = \{(a_1, a_2, \ldots, a_k - |x|, x) \mid a_i \in \{0, 1\}\}$

Theorem

A graph of degree $\Delta$ may be colored with $\Delta + 1$ colors in time $O(\Delta \log n)$ on a distributed/parallel system.
Independent Set

\[ U_x = \{(a_1, a_2, \ldots, a_{k-|x|}, x) \mid a_i \in \{0, 1\}\} \]

- \( V' \subset V \) with \( \forall a, b \in V' \) : \((a, b) \not\in E\) is called independent set.

- \( \alpha(G) = \max \{ |V'| \mid V' \subset V \land \forall a, b \in V' : (a, b) \not\in E \} \).

- The problem of finding an independent set of size \( n/2 \) is NP-complete.

- A independent set \( I \) is call maximal iff there is no larger independent set containing \( I \).

- This is called MIS.

- Finding the lexicographical first MIS is P-complete.

- Coloring and independent set have some relationship.

- The nodes of one color form an independent set.
Independent Set and Coloring

Idea: use a coloring to compute a MIS:

1. For all nodes set $b(v) = 0$.
2. For all $i$ from 1 to $\chi(G)$ do
   1. if $b(v) = 0$ then set $b(v) = 1$.
   2. if some neighbor of $v$ has $b(v) = 1$ then set $b(v) = -1$.

This will produce in time is $O(\chi(G))$. 

$$U_x = \{(a_1, a_2, \ldots a_{k-|x|}, x) \mid a_i \in \{0, 1\}\}$$
Independent Set and Coloring

\[ U_x = \{(a_1, a_2, \ldots, a_{|x|-1}, x) \mid a_i \in \{0, 1\}\} \]

**Theorem**

There is a deterministic \( O(\log^* n) \) time algorithm for MIS on cycles, trees and bounded degree graphs of \( n \) processors.

**Theorem**

There is a deterministic \( O(\Delta \log n) \) time algorithm for MIS on any graph of \( n \) processors.

**Theorem**

Any deterministic distributed algorithm needs at least \( 1/2(\log^* n - 1) \) rounds to color a cycle of length \( n \) with 3 colors.

**Theorem**

Any deterministic distributed MIS algorithm on a cycle of length \( n \) uses \( 1/2(\log^* n - 3) \) rounds.
Independent Set and Coloring

U_x = \{(a_1, a_2, \ldots, a_k - |x|, x) \mid a_i \in \{0, 1\}\}

**Theorem**

*Any deterministic distributed MIS algorithm on a cycle of length n uses \(1/2(\log^* n - 3)\) rounds.*

- We have a lower bound of \(1/2(\log^* n - 1)\) for 3-coloring a cycle of length n.
- We have to show, given a MIS we may color the cycle in just one more round.
- We may assume we have some cyclic order on the nodes.
- Each node which is in the MIS colors itself with color 1.
- Each node which is in the MIS sends a 2 to the neighbor to the right.
- Each node receiving a 2 colors itself with color 2.
- Each node not receiving a 2 colors itself with color 3.
- There are no non-colored nodes (see definition of MIS).
Planar graphs

\[ U_x = \{(a_1, a_2, \ldots, a_{k-|x|}, x) \mid a_i \in \{0, 1\}\} \]

A graph \( G = (V, E) \) is called planar if there is an embedding into the plane without crossings.

- It holds for planar graphs that \( |E| \leq 3 \cdot |V| - 6 \).
- \( K_{3,3} \) and \( K_5 \) are not planar.
- Planar graphs have nodes of degree \( \leq 5 \).
- Planar graphs are 4 colorable.
- A window is a closed region which is limited by a path.
Outer planar graphs

Definition
A graph $G = (V, E)$ is outerplanar if there is an embedding into the plane without crossings such that all nodes lie on the outer window.

- It holds for outerplanar graphs that $|E| \leq 2 \cdot |V| - 3$.
- $K_{2,3}$ and $K_4$ are outerplanar.
- Outer planar graphs have nodes with degree $\leq 2$.
- Outer planar graphs are 3 colorable.
- The inner windows form a tree.
Overview of the Algorithm

Let $G$ be a connected outerplanar graph.

- Compute the outer edges.
- Direct the outer edges such that they form a cycle.
- Determine the location and orientation of the inner edges and double those to two directed edges.
- Compute a directed cycle for every window.
- Color every window independently.
- Determine the tree structure of the windows i.e. every cycle corresponds to nodes in the tree.
- Combine the cycles into pairs of layers of bigger correctly colored objects.
- Repeat the last step until the whole graph is colored correctly.

$$U_x = \{ (a_1, a_2, \ldots, a_{k-|x|}, x) \mid a_i \in \{0, 1\} \}$$
Details of the algorithm.

Compute the outer edges.
  - Test for edge \( \{v, w\} \) if \( G \setminus \{v, w\} \) separates.
  - A test: \( O(\log^2 n) \) time using \( O(n^2 / \log^2 n) \) processors.
  - Total: \( O(\log^2 n) \) time with \( O(n^3 / \log^2 n) \) processors.

Direct the outer edges such that they form a cycle.
  - Create for every outer edge two opposing directed edges.
  - Sort the edges lexicographical in \( K_1, K_2, \ldots, K_{2 \cdot m} \).
  - Successor of \( K_x = (i, j) \) is \( K_{2 \cdot j} = (r, s) \) if \( s \neq i \).
  - Successor of \( K_x = (i, j) \) is \( K_{2 \cdot j+1} = (r, s) \) if \( s \neq i \).
  - Choose a cycle.
  - Determine the position of every node on the cycle.
  - Total running time: \( O(\log n) \) time with \( O(n) \) processors.

\[
U_x = \{(a_1, a_2, \ldots, a_{k - |x|}, x) \mid a_i \in \{0, 1\}\}
\]
Details of the algorithm.

\[ U_x = \{(a_1, a_2, \ldots, a_{k-|x|}, x) | a_i \in \{0, 1\}\} \]

- Determine the location and orientation of the inner node.
  - Sort the inner edges \( \{a, a_1\}, \{a, a_2\}, \{a, a_3\}, \cdots \) at the node \( a \) is given by the location of the nodes \( a_1, a_2, \cdots \) on the cycle.
  - Total running time: \( O(\log n) \) time with \( O(n) \) processors.

- Create for every outer edge two opposing directed edges.

- Determine the directed cycle in every window.
  - Compute new successors using the order of the edges at every node.
  - Compute new cycles and representatives.
  - Total running time: \( O(\log n) \) with \( O(n) \) processors.
Details of the algorithm.

- Color every window independently.
  - Total running time: $O(\log^* n)$ with $O(n)$ processors.

- Determine the tree structure of the windows i.e. every cycle corresponds to nodes in the tree.
  - Using the inner edges the neighborhood can be read directly.
  - The depth of the nodes can be computed using the ranking in the list.
  - Total running time: $O(\log n)$ using $O(n)$ processors.

- Combine the cycles into pairs of layers of bigger correctly colored objects.
  - The child cycle orients itself to the coloring of the parent cycle.
  - Total: $O(1)$ time with $O(n)$ processors.

- Repeat the last step until the whole graph is colored correctly.
  - Total: $O(\log n)$ time with $O(n)$ processors.

- \[ U_x = \{(a_1, a_2, \ldots, a_k - |x|, x) \mid a_i \in \{0, 1\}\} \]
Facts

\[ U_x = \{(a_1, a_2, ..., a_{k-|x|}, x) \mid a_i \in \{0, 1\}\} \]

**Theorem:**

A two-connected outerplanar graph can be colored with three colors using time \( O(\log^2 n) \) and \( O(n^3 / \log^2 n) \) processors.

**Proof:** See above.

**Theorem:**

An outerplanar graph can be colored with three colors using time \( O(\log^2 n) \) and \( O(n^3 / \log^2 n) \) processors.

**Proof:** Use similarly the tree structure of the two connected components.

**Theorem:**

A planar graph can be colored with six colors in time \( O(\log^2 n) \) with \( O(n) \) processors.

**Proof:** See exercise.
Theorem:

The edges of an outerplanar graph $G$ with $\Delta(G) \leq 3$ and known embedding in the plane can be colored using three colors in time $O(\log^2 n)$ with $O(n^2)$ processors.

Idea if the proof: Similar procedure then above.

Theorem:

The edges of an outerplanar graph $G$ with known embedding in the plane can be colored with three colors in time $O(\log^3 n)$ with $O(n^2)$ colors.

Proof: See literature.
Simulations

Theorem:
A program $A$ for a CREW PRAM with $P_A(n)$ processors and running time $T_A(n)$ can be simulated with an EREW PRAM with $P_A(n)^2$ processors in time $O(T_A(n) \log n)$.

Theorem:
A program $A$ for a CRCW PRAM with $P_A(n)$ processors and running time $T_A(n)$ can be simulated with an CREW PRAM with $P_A(n)^2$ processors in time $O(T_A(n) \log n)$.

Theorem:
A program $A$ for a CRCW PRAM with $P_A(n)$ processors and running time $T_A(n)$ can be simulated with an EREW PRAM with $P_A(n)^2$ processors in time $O(T_A(n) \log n)$.
Simulations II

Theorem:
A program $A$ for a CREW PRAM with $P_A(n)$ processors and running time $T_A(n)$ can be simulated with an EREW PRAM with $P_A(n)$ processors in time $O(T_A(n) \log n)$.

Theorem:
A program $A$ for a CRCW PRAM with $P_A(n)$ processors and running time $T_A(n)$ can be simulated with an CREW PRAM with $P_A(n)$ processors in time $O(T_A(n) \log n)$.

Theorem:
A program $A$ for a CRCW PRAM with $P_A(n)$ processors and running time $T_A(n)$ can be simulated with an EREW PRAM with $P_A(n)$ processors in time $O(T_A(n) \log n)$.
Literature for this chapter

\[ U_x = \{(a_1, a_2, \ldots, a_{k-|x|}, x) \mid a_i \in \{0, 1\}\} \]
